Technical Proposal

Development of the LLWB Women Experts Roster and Online Platform

Understanding

LLWB requires a secure, bilingual, responsive platform through which women experts can submit profiles for review and through which visitors can search approved profiles. Authorized staff need a manageable interface for approvals, categories, and content, with documentation and training enabling independent administration.

Proposed approach

The delivery will use short feedback cycles with LLWB. The first phase confirms information architecture, profile fields, privacy choices, categories, bilingual terminology, approval policy, and acceptance criteria. The implementation then separates public discovery from authenticated submission and administration, ensuring that unapproved or private information cannot leak through public endpoints.

Proposed stack

Next.js and React with TypeScript for the responsive web interface; NestJS and TypeScript for a validated REST API; PostgreSQL with Prisma for relational data and moderation history; Docker for reproducible environments; GitHub Actions for automated checks; AWS deployment using least-privilege infrastructure and documented backup/rollback procedures.

Functional scope

The platform will include expert registration, profile submission, consent capture, reviewer approval/rejection with reasons, category management, approved-only public search, filters for agreed professional criteria, role-based administration, audit records, Arabic RTL support, English support, responsive layouts, error handling, and a documented staff handover.

Indicative 10-week plan

Weeks	Deliverables
1–2	Discovery, requirements confirmation, data/privacy review, information architecture, UX wireframes
3	Technical architecture, database design, bilingual content model, approval policy, prototype review
4–6	Registration, profile forms, validation, PostgreSQL persistence, public directory, search/filtering
5–7	Reviewer/admin interface, role controls, categories, audit records, privacy/security hardening
7–8	Unit/integration/E2E tests, accessibility and responsive checks, UAT fixes
9	Deployment, domain/TLS configuration, backup and rollback runbook, operational verification
10	Documentation, staff training, handover, launch checklist, agreed post-launch support

Quality and security

The API will enforce authorization independently of the interface. Public response DTOs will contain only approved fields. Validation, rate limiting, secure authentication, audit logging, dependency checks, encrypted transport, backup testing, retention rules, and a clear incident process will be included in the final security configuration. Real production values and credentials will never be committed to source control.

Handover

LLWB will receive the administrator guide, data dictionary, deployment/runbook documentation, test and UAT summary, backup/restore procedure, and a live training session covering profile review, categories, content, account management, and common troubleshooting.

Assumptions to confirm

Hosting ownership, final bilingual copy, categories and filters, required privacy/consent wording, email delivery provider, moderation roles, retention/deletion rules, post-launch support period, and the required legal/financial registration documents.

Relevant evidence

WaveMark full-stack experience supports the web/API delivery approach; the public GitHub portfolio supports API, search, Docker, evaluation, and automation capabilities; the new Women Experts Roster portfolio project demonstrates the proposed directory and moderation architecture. The portfolio project is not an LLWB deployment and contains no real expert data.
